

Geometry

(page 1)

In the triangles  $OIE$  and  $OIC$ ,

$$CI = IE$$

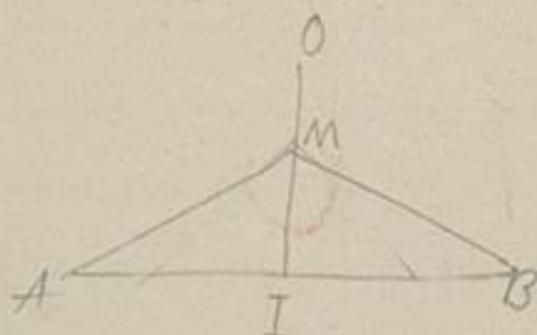

$OI$  is common

$\angle OIC = \angle OIE$ ,  $OI$  being perpendicular

$\therefore \triangle OIE = \triangle OIC$  Hence corresponding sides  $OE$  and  $OC$  which are opposite the equal angles  $\angle OIC$  and  $\angle OIE$ , must be equal to one another.

Converse proposition. If the two obliques  $OC$  and  $OE$  are equal to one another, then their perpendiculars  $IC$  and  $IE$  will be equal. Prove. The triangle  $COE$  is the isosceles because the sides  $OC$  and  $OE$  are equal to one another (by hypothesis) therefore if we draw perpendicular  $OI$  from the vertex  $O$  to the base  $CE$  it will bisect that base by the property of isosceles triangle, therefore  $IC$  is equal to  $IE$ , hence the proposition.

2.

Let  $OI$  be the perpendicular bisector of the straight line  $AB$ , then we are to prove  $OI$  is the locus of points in the plane equidistant from the extreme points of  $AB$ .

Since in order to establish a locus two propositions are always necessary, we will first prove the direct and then the second proposition.

OI

Direct. Every point  $M$  on the perpendicular bisector is the equidistant from the extremities  $A$  and  $B$  of the str. line  $AB$ . because the triangles  $AIM$  and  $BIM$ ,  $MI$  is common

$$AI = BI \text{ (by hypothesis)}$$

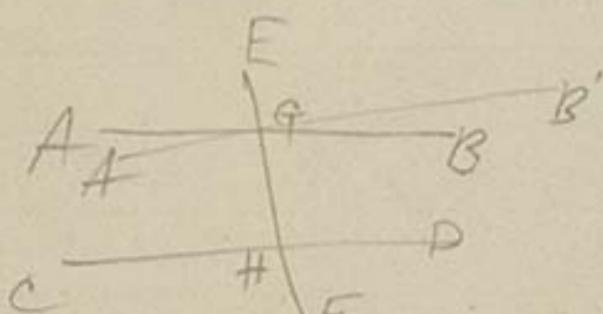

$$\angle MIB = \angle MIA \text{ (OI being perpendicular bisector of AB)}$$

$$\therefore \triangle MIA \cong \triangle MIB, \therefore MA = MB, \text{ that is}$$

every point  $M$  on  $OI$  is equidistant from  $A, B$ .

Converse. Every point  $M$  which is equidistant from  $A, B$  will be on  $OI$ ; because in the triangle  $MAB$ ,  $MA = MB$ , therefore  $MAB$  is the isosceles, therefore

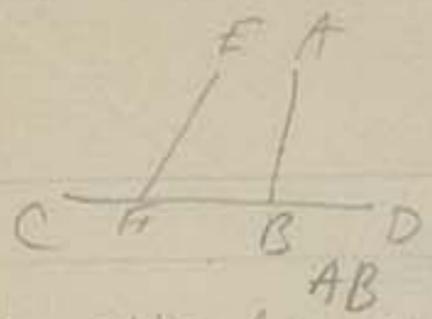

if we draw <sup>the</sup> perpendicular  $OI$  from the vertex  $M$  to the base  $AB$  it will bisect  $AB$  by the properties of isosceles triangle,  $\therefore M$  must be on  $OI$  which is perpendicular bisector of  $AB$ . Thus we have proved by the two propositions (direct and its converse) that Perpendicular bisector of a str. line is the locus of pts. in the plane equidistant from the extremities of that str. line.

If two str. lines  $AB, CD$  be cut by a secant  $EF$  and the sum of the two interior angles  $BGH$  and  $GHD$  on the same side of the secant is not equal to two right angles, then  $AB$  and  $CD$  are not parallel

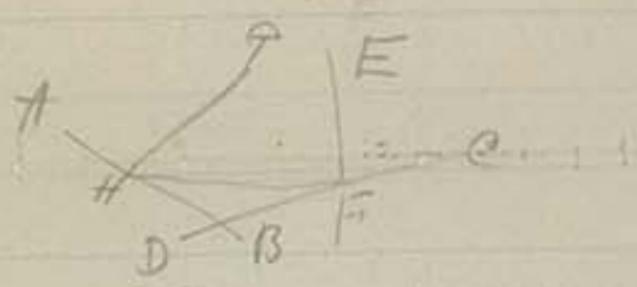

Cor. I If two str. lines  $AB, CD$  be cut by a secant  $EF$  and the sum of the two interior angles  $BGH$  and  $GHD$  on the same side of the secant  $EF$  is less than two right angles, then  $AB, CD$  will meet on that side of  $EF$  on which  $\angle BGH$  and  $\angle GHD$  are situated. Because if we draw the parallel line  $A'B'$ ,  $\angle B'GH$  being greater than  $\angle BGH$ ,  $GB$  will fall within  $A'B'$ ,  $\therefore GB$  and  $HD$  will meet. (This cor. was adopted by Euclid as the axiom)

Cor. 2.

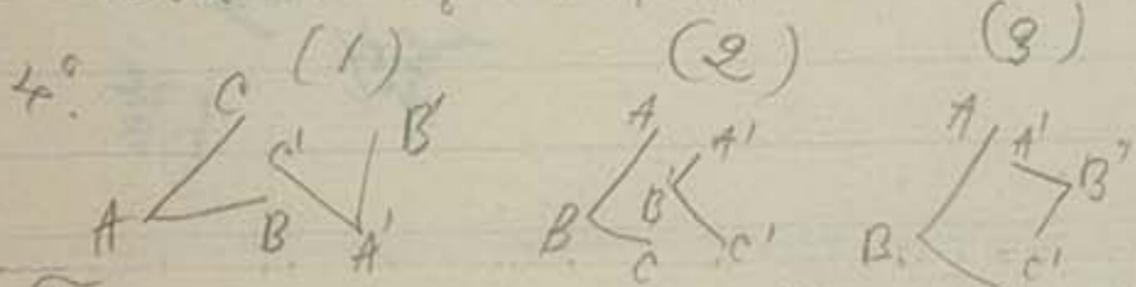

A perpendicular  $AB$  and an oblique  $EF$  drawn to a straight line  $CD$  will meet one another because the sum of the  $\angle EFB$  and  $\angle ABF$  is less than  $2$  R.L.s.

Cor. 3.

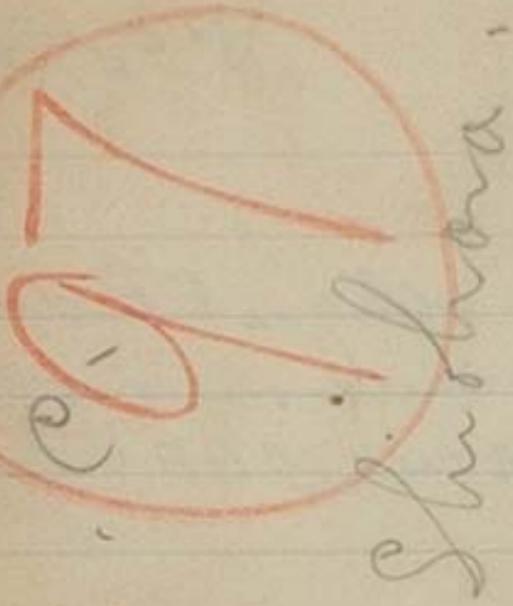

If two str. lines  $EF$  and  $GH$  are perpendicular respectively to  $AB$  and  $CD$  which are cut one another, then  $EF$  and  $GH$  will meet one another. Because if we draw  $FH$ , it is evident the sum of  $\angle GHF$  and  $\angle EFH$  is less than two right angles.

These are three cases (1) if  $AC$  and  $AB$  are respectively  $\perp$  to  $A'C'$  and  $A'B'$ , and  $A'C'$  drawn toward  $AC$ ,  $A'B'$  drawn toward  $A'B'$ , then  $\angle CAB = \angle A'A'B'$ . Because if we turn the  $\angle B'A'C'$  toward right hand around vertex  $A'$  through a right angle then  $\angle CAB$ ,  $\angle A'A'B'$  have their sides parallel each to each and the parallel sides drawn in the same direction.  $\angle CAB = \angle A'A'B'$ . (2) if  $A'B'$  and  $B'C'$  are respectively  $\perp$  to  $AB$  and  $BC$  and  $A'B'$ ,  $B'C'$  drawn away from  $AB$  and  $BC$ , then  $\angle ABC + \angle A'B'C' = 2$  R.L.s. Because if we turn  $A'B'C'$  toward right hand around the vertex  $B'$  through a R.L. then the two angles have their sides parallel each to each and the two parallel sides drawn in the same direction and the other in the contrary direction.  $\angle ABC + \angle A'B'C' = 2$  R.L.s. (3)

In the (3) case it is just equal with second.

4th Grade.
